Controllers

Routing

Models

Controllers

Controllers handle the logic of your application.

They receive input from the user, interact with models to fetch or manipulate data, and return the appropriate response to the user.

Routing

Routing defines how an application responds to specific URLs.

In Laravel, routes are defined in the routes/web.php file and can be used to handle HTTP requests, direct users to appropriate controllers, and generate dynamic URLs.

Models

Models represent the structure of your application's data and provide an interface to interact with the database. They encapsulate the business logic and handle database operations, making it easy to work with data.
